Chapter I

Introduction

We consider births in Germany. Question (two variants):

- (i) What is the probability of having a girl?
- (ii) Is it more likely to have a boy than a girl?

Empirical data from statistical sample yields the gender of N births:

$$k \text{ girls } (1), \quad N - k \text{ boys } (0).$$

The relative frequencies are given by

$$\widehat{p}(1) = \frac{k}{N}, \quad \widehat{p}(0) = \frac{N-k}{N} = 1 - \widehat{p}(1)$$

and serve as a metric of the data (descriptive statistics).

Naive answers to the above questions read:

- (i) The sought probability is given by $\widehat{p}(1)$.
- (ii) Yes if and only if $\widehat{p}(0) > \widehat{p}(1)$.

Criticism:

- The answers are based on only one sample or data set.
- The sample size and the variability of the data are not taken into account.

Therefore we will consider

inferential statistics (see Chapters ?? and ??)

to infer properties of an underlying probability distribution. This, in turn, requires a

mathematical model (see Chapters II and III)

of the underlying random mechanism.

Chapter II

Probability Theory – Discrete Case

In this section we aim at modelling and analyzing random experiments with at most countably infinite outcomes (discrete case).

In the sequel let Ω be a finite or a countably infinite set. The set Ω is a model for the possible results of a random experiment.

1 Discrete Probability Spaces

Definition 1. The set Ω is called *sample space*. Its elements $\omega \in \Omega$ are called *outcomes*. Any subset $A \subseteq \Omega$ of Ω is called an *event*.

Example 2. Consider a fair coin with head (1) and tail (0) that is tossed twice. The corresponding sample space is given by

$$\Omega = \{(1,1), (1,0), (0,1), (0,0)\} = \{1,0\}^2.$$

The event $A = \{(1,1), (1,0)\}$ contains all outcomes with 1 in the first toss.

Clearly, we may also use this sample space as a model for two-stage processes having two outcomes (e.g., yes/no) per stage, e.g., a two-stage production process where in each stage some tolerance level is satisfied or not.

Terminology: We say that the event $A \subseteq \Omega$ occurs if $\omega \in A$.

Notation: For sets A, B we write $A \subseteq B$ if every element of A is also an element of B, and we write A = B if $A \subseteq B$ and $B \subseteq A$. The empty set containing no elements is denoted by \emptyset . The cardinality of a set A is denoted by |A|.

Definition 3. Let $A, B \subseteq \Omega$ be events. The *union*, the *intersection*, and the *difference* of A and B as well as the *complement* of A are defined by

$$A \cup B = \{ \omega \in \Omega \colon \omega \in A \text{ or } \omega \in B \},$$

$$A \cap B = \{ \omega \in \Omega \colon \omega \in A \text{ and } \omega \in B \},$$

$$A \setminus B = \{ \omega \in \Omega \colon \omega \in A \text{ and } \omega \notin B \},$$

$$A^{c} = \Omega \setminus A = \{ \omega \in \Omega \colon \omega \notin A \},$$

respectively.

Remark 4. Foe events $A, B, C \subseteq \Omega$ we have

$$A \cap (B \cup C) = (A \cap B) \cup (A \cap C),$$

$$A \cup (B \cap C) = (A \cup B) \cap (A \cup C),$$

$$(A \cap B)^{c} = A^{c} \cup B^{c},$$

$$(A \cup B)^{c} = A^{c} \cap B^{c},$$

$$A \setminus B = A \cap B^{c}.$$

Definition 5. The (countable) union of events $A_1, A_2, A_3, \ldots \subseteq \Omega$ is defined by

$$\bigcup_{i=1}^{\infty} A_i = \{ \omega \in \Omega \colon (\exists i \in \mathbb{N} \colon \omega \in A_i) \}.$$

The events $A_1, A_2, A_3, \ldots \subseteq \Omega$ are pairwise disjoint if $A_i \cap A_j = \emptyset$ for all $i, j \in \mathbb{N}$ with $i \neq j$.

Remark 6. Clearly, we can express the union of finitely many events as a countable union, i.e., for $n \in \mathbb{N}$ and events $A_1, \ldots, A_n \subseteq \Omega$ we have

$$\bigcup_{i=1}^{n} A_i = A_1 \cup \ldots \cup A_n = \bigcup_{i=1}^{\infty} A_i$$

if we put $A_i = \emptyset$ for i > n.

We are now going to assign probabilities P(A) to events $A \subseteq \Omega$.

Definition 7. The set

$$\mathcal{P}(\Omega) = \{A \colon A \subseteq \Omega\}$$

of all subsets of Ω is called *power set* of Ω .

Example 8. The power set of $\Omega = \{0, 1\}$ is given by

$$\mathcal{P}(\Omega) = \{\varnothing, \{0\}, \{1\}, \Omega\}.$$

Moreover, we have $|\mathcal{P}(\Omega)| = 2^{|\Omega|}$.

Definition 9. A function $P: \mathcal{P}(\Omega) \to \mathbb{R}$ is a probability measure (on Ω) (or probability distribution (on Ω)) if

- (i) $0 \le P(A) \le 1$ for all $A \subseteq \Omega$,
- (ii) $P(\Omega) = 1$,
- (iii) for all pairwise disjoint events $A_1, A_2, \ldots \in \mathcal{P}(\Omega)$ we have

$$P\left(\bigcup_{i=1}^{\infty} A_i\right) = \sum_{i=1}^{\infty} P(A_i).$$
 (\sigma-additivity)

In such a case the triple $(\Omega, \mathcal{P}(\Omega), P)$ is called a discrete probability space.

Proposition 10. Let P be a probability measure on Ω and let $A, B \in \mathcal{P}(\Omega)$. Then we have

(i)
$$A \cap B = \emptyset \Rightarrow P(A \cup B) = P(A) + P(B)$$
 (additivity),

(ii)
$$A \subseteq B \Rightarrow P(B \setminus A) = P(B) - P(A)$$
,

(iii)
$$A \subseteq B \Rightarrow P(A) \le P(B)$$
 (monotonicity),

(iv)
$$P(A^{c}) = 1 - P(A),$$

(v)
$$P(A \cup B) = P(A) + P(B) - P(A \cap B)$$
.

Proof. ad (i): Since $A \cap B = \emptyset$, we have

$$A \cup B = A \cup B \cup \varnothing \cup \varnothing \cup \dots$$

for pairwise disjoint events and thus the σ -additivity of P shows

$$P(A \cup B) = P(A) + P(B) + \sum_{i=3}^{\infty} P(\varnothing).$$

Since $P(A \cup B) \in [0, 1]$, we have $P(\emptyset) = 0$.

ad (ii)-(v): See Exercise 1.1.

2 Probability Mass Functions

Definition 1. Let P be a probability measure on Ω . The function $p \colon \Omega \to \mathbb{R}$ defined by

$$p(\omega) = P(\{\omega\})$$

is called probability mass function (associated to P).

Proposition 2.

(i) For P and p according to Definition 1 and for every $A \subseteq \Omega$ we have

$$P(A) = \sum_{\omega \in A} p(\omega).$$

In particular, P is uniquely determined by p.

(ii) Every probability mass function $p: \Omega \to \mathbb{R}$ satisfies

$$\forall \omega \in \Omega \colon 0 \le p(\omega) \le 1 \quad \land \quad \sum_{\omega \in \Omega} p(\omega) = 1.$$
 (1)

(iii) Every function $p: \Omega \to \mathbb{R}$ satisfying (1) defines a probability measure P on Ω by

$$P(A) = \sum_{\omega \in A} p(\omega)$$

for $A \subseteq \Omega$.

Proof. Since Ω is countable, every $A \subseteq \Omega$ is countable and can thus be expressed as a countable union $A = \bigcup_{\omega \in A} \{\omega\}$ of pairwise disjoint sets.

ad (i): The σ -additivity of P yields for $A \subseteq \Omega$

$$P(A) = P\left(\bigcup_{\omega \in A} \{\omega\}\right) = \sum_{\omega \in A} P(\{\omega\}) = \sum_{\omega \in A} p(\omega).$$

ad (ii): Use part (i) with $A = \Omega$ and note that $P(\Omega) = 1$.

ad (iii): Verify the conditions of Definition 1.9.

Example 3. Let Ω be finite with $|\Omega| = n \in \mathbb{N}$. For $\omega \in \Omega$ we put

$$p(\omega) = \frac{1}{n}.$$

Then p satisfies (1) and the associated probability measure P is given by

$$P(A) = \frac{|A|}{|\Omega|}$$

for every $A \subseteq \Omega$. Hence the calculation of probabilities is based on counting elements.

Definition 4. The probability measure P according to Example 3 is called the *discrete* uniform distribution (on the finite set Ω).

Example 5. Consider a fair coin that is tossed twice, cf. Example 1.2. We model this random experiment by using the discrete uniform distribution P on

$$\Omega = \{(1,1), (1,0), (0,1), (0,0)\}.$$

The events

$$A = \{(1,1), (1,0)\} =$$
"1 in the first toss",
 $B = \{(1,1), (0,1)\} =$ "1 in the second toss"

satisfy

$$P(A) = \frac{2}{4} = \frac{1}{2} = P(B),$$

$$P(A \cap B) = P(\{(1, 1)\}) = \frac{1}{4} = P(A) \cdot P(B),$$

$$P(A \cup B) = P(\{(1, 1), (1, 0), (0, 1)\}) = \frac{3}{4}.$$

Example 6. Consider a two-stage production process where in each process a tolerance level is satisfied (1) or not (0). We model this by

$$\Omega = \{(1,1), (1,0), (0,1), (0,0)\}$$

and the (fictional) probability mass function

The events

$$A = \{(1,1), (1,0)\}$$
 = "tolerance level satisfied in first stage",
 $B = \{(1,1), (0,1)\}$ = "tolerance level satisfied in second stage"

satisfy

$$P(A) = 0.89,$$

 $P(B) = 0.81,$
 $P(A \cap B) = 0.8 \neq 0.7209 = P(A) \cdot P(B).$

3 Conditional Probability and Independence

In the sequel let $(\Omega, \mathcal{P}(\Omega), P)$ be a discrete probability space.

Question: How do we change the probability measure P if we know that a certain event $B \subseteq \Omega$ has occured.

Definition 1. For $A, B \subseteq \Omega$ with P(B) > 0 the conditional probability of A given B is defined by

$$P(A \mid B) = \frac{P(A \cap B)}{P(B)}.$$

Example 2. Let P be the discrete uniform distribution on a finite set Ω . For $A, B \subseteq \Omega$ with $B \neq \emptyset$ we have P(B) > 0 and

$$P(A \mid B) = \frac{|A \cap B|}{|\Omega|} \cdot \frac{|\Omega|}{|B|} = \frac{|A \cap B|}{|B|}.$$

In Example 2.5 (fair coin tossed twice "independently") we thus have

$$P(A | B) = P(B | A) = \frac{1}{2}$$

for $A = \{(1,1), (1,0)\}$ and $B = \{(1,1), (0,1)\}.$

Example 3. In Example 2.6 (two-stage production process) we have

$$P(A \mid B) = \frac{P(\{(1,1)\})}{P(\{(1,1),(0,1)\})} = \frac{0.8}{0.81} \approx 0.9876$$

and

$$P(B \mid A) = \frac{P(\{(1,1)\})}{P(\{(1,1),(1,0)\})} = \frac{0.8}{0.89} \approx 0.8988$$

for
$$A = \{(1,1), (1,0)\}$$
 and $B = \{(1,1), (0,1)\}.$

Remark 4. Let p be the probability mass function associated to P, and let $B \subseteq \Omega$ with P(B) > 0. For $A \subseteq \Omega$ we have

$$P(A \mid B) = \frac{1}{P(B)} \cdot \sum_{\omega \in A \cap B} p(\omega) = \sum_{\omega \in A} q(\omega),$$

where

$$q(\omega) = \begin{cases} \frac{p(\omega)}{P(B)}, & \text{if } \omega \in B, \\ 0, & \text{else.} \end{cases}$$

Then $Q \colon \mathcal{P}(\Omega) \to \mathbb{R}$ given by

$$Q(A) = P(A \mid B)$$

defines a probability measure on Ω with probability mass function q.

Definition 5. Two events $A, B \subseteq \Omega$ are independent if

$$P(A \cap B) = P(A) \cdot P(B).$$

Remark 6. Let P(B) > 0. Then we have

$$A, B \text{ independent} \Leftrightarrow P(A \mid B) = P(A).$$

Example 7. In Example 2.5 (fair coin tossed twice "independently") the events A and B are independent. In Example 2.6 (two-stage production process) the events A and B are dependent.

Proposition 8 (Bayes's law). Let $n \in \mathbb{N}$ and $\{B_1, \ldots, B_n\} \subseteq \mathcal{P}(\Omega)$ be a partition¹ of Ω with $P(B_i) > 0$ for all $i = 1, \ldots, n$.

(i) For all $A \subseteq \Omega$ we have

$$P(A) = \sum_{i=1}^{n} P(A \mid B_i) \cdot P(B_i).$$

(ii) For all $A \subseteq \Omega$ with P(A) > 0 and for all k = 1, ..., n we have

$$P(B_k | A) = \frac{P(A | B_k) \cdot P(B_k)}{\sum_{i=1}^{n} P(A | B_i) \cdot P(B_i)}.$$

Proof. ad (i): Since $\{B_1, \ldots, B_n\}$ is a partition, we obtain for every $A \subseteq \Omega$

$$A = A \cap \left(\bigcup_{i=1}^{n} B_i\right) = \bigcup_{i=1}^{n} (A \cap B_i)$$

with pairwise disjoint sets $A \cap B_1, \ldots, A \cap B_n \subseteq \Omega$. Hence we get

$$P(A) = \sum_{i=1}^{n} P(A \cap B_i).$$

¹A partition of Ω is a family of non-empty pairwise disjoint sets $B_1, B_2, ... \subseteq Ω$ with $\bigcup_{i=1}^n B_i = Ω$.

Since $P(B_i) > 0$ for all i = 1, ..., n, the conditional probabilities $P(A | B_i)$ are well-defined such that $P(A \cap B_i) = P(A | B_i) \cdot P(B_i)$.

ad (ii): If P(A) > 0, the conditional probability $P(B_k | A)$ is well-defined and we have

$$P(B_k | A) \cdot P(A) = P(B_k \cap A) = P(A \cap B_k) = P(A | B_k) \cdot P(B_k)$$

for all k = 1, ..., n. Use part (i).

4 Random Variables

In the sequel let $(\Omega, \mathcal{P}(\Omega), P)$ be a discrete probability space.

Question: How can we describe particular aspects of a random experiment (rather than the full experiment)?

Example 1. Consider a fair die that is rolled twice independently, i.e., we consider a discrete uniform distribution P on $\Omega = \{1, ..., 6\}^2$. Particular aspects could be:

- (i) "number of pips in first die roll",
- (ii) "number of pips in second die roll",
- (iii) "sum of pips".

In the sequel let $\mathfrak{X} \subseteq \mathbb{R}$ be finite or countably infinite. We will typically consider $\mathfrak{X} \subset \mathbb{N}_0$.

Definition 2. A function $X: \Omega \to \mathfrak{X}$ is called a random variable (with values in \mathfrak{X}). Its function values $x = X(\omega) \in \mathfrak{X}$ are called realizations of X.

Example 3 (Continuation of Example 1). The first two aspects are described by $\mathfrak{X} = \{1, \dots, 6\}$ and the random variables $X_1, X_2 \colon \Omega \to \mathfrak{X}$ given by

$$X_1(\omega) = \omega_1, \quad X_2(\omega) = \omega_2$$

for $\omega = (\omega_1, \omega_2) \in \Omega$. The third aspect is described by $\mathfrak{S} = \{2, \dots, 12\}$ and the random variable $S: \Omega \to \mathfrak{S}$ given by

$$S(\omega) = X_1(\omega) + X_2(\omega) = \omega_1 + \omega_2.$$

In the sequel let $X : \Omega \to \mathfrak{X}$ be a random variable. In many cases one is just interested in the probabilities

$$P_X(A) = P(\{\omega \in \Omega \colon X(\omega) \in A\})$$

for $A \subseteq \mathfrak{X}$ and in particular in

$$p_X(x) = P_X(\{x\}) = P(\{\omega \in \Omega : X(\omega) = x\})$$

for $x \in \mathfrak{X}$.

II.4. Random Variables 9

Example 4 (Continuation of Example 3). For $x \in \{1, ..., 6\}$ we have

$$p_{X_1}(x) = p_{X_2}(x) = \frac{1}{6},$$

and p_S is given by

Proposition 5. The following holds true:

- (i) $p_X : \mathfrak{X} \to \mathbb{R}$ is a probability mass function,
- (ii) P_X is the associated probability measure on \mathfrak{X} , i.e., for all $A \subseteq \mathfrak{X}$ we have

$$P_X(A) = \sum_{x \in A} p_X(x).$$

Definition 6. P_X and p_X are called distribution and probability mass function of X, respectively.

Example 7 (Continuation of Example 4). A rod graph can be used to illustrate the probability mass functions p_{X_1} and p_S , see Figure 4.1.

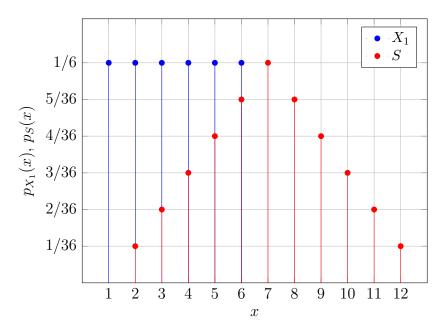

Figure 4.1: Probability mass functions p_{X_1} and p_S from Example 4.

Definition 8. Two random variables $X_1, X_2 : \Omega \to \mathfrak{X}$ are identically distributed if

$$P_{X_1}(A) = P_{X_2}(A)$$

for all $A \subseteq \mathfrak{X}$.

Example 9 (Continuation of Example 4). P_{X_1} and P_{X_2} are both the discrete uniform distribution on $\{1, \ldots, 6\}$. Hence X_1 and X_2 are identically distributed.

Proposition 10 (Criterion for identical distributions). $X_1, X_2: \Omega \to \mathfrak{X}$ are identically distributed if and only if

$$p_{X_1}(x) = p_{X_2}(x)$$

for all $x \in \mathfrak{X}$.

Proof. Use Proposition 5.

Remark 11. The case of a multivariate random variable (random vector)

$$X = (X_1, \ldots, X_n) \colon \Omega \to \mathfrak{X}$$

with an at most countably infinite set $\mathfrak{X} \subseteq \mathbb{R}^n$ is treated analogously. The components X_i of X are random variables.

Example 12 (Continuation of Example 3).

(i) For $\mathfrak{X} = \{1, \ldots, 6\}^2$ and $x = (x_1, x_2) \in \mathfrak{X}$ we have

$$p_{(X_1,X_2)}(x) = P(\{\omega \in \Omega : \omega = x\}) = P(\{x\}) = \frac{1}{36}.$$

Hence $P_{(X_1,X_2)}$ is the discrete uniform distribution on \mathfrak{X} .

(ii) For $\mathfrak{X} = \{(x_1, s) \in \mathbb{N}^2 : 1 \le x_1 \le 6 \land x_1 + 1 \le s \le x_1 + 6\}$ and $(x_1, s) \in \mathfrak{X}$ we have

$$p_{(X_1,S)}(x_1,s) = P(\{\omega \in \Omega : \omega_1 = x_1 \wedge \omega_1 + \omega_2 = s\}) = \frac{1}{36}.$$

Hence $P_{(X_1,S)}$ is the discrete uniform distribution on \mathfrak{X} .

In the sequel we use

$$\{X = x\} = \{\omega \in \Omega \colon X(\omega) = x\},\$$
$$\{X \in A\} = \{\omega \in \Omega \colon X(\omega) \in A\},\$$

and we consider random variables X_1, \ldots, X_n on $(\Omega, \mathcal{P}(\Omega), P)$ taking values in an at most countably infinite set \mathfrak{X} .

Definition 13. X_1, \ldots, X_n are *independent* if for all $A_1, \ldots, A_n \subseteq \mathfrak{X}$ we have

$$P\left(\bigcap_{i=1}^{n} \{X_i \in A_i\}\right) = \prod_{i=1}^{n} P(\{X_i \in A_i\}).$$

Example 14 (Continuation of Example 3).

(i) For $\mathfrak{X} = \{1, \ldots, 6\}$ and $A_1, A_2 \subseteq \mathfrak{X}$ we have

$$P(\{X_1 \in A_1\} \cap \{X_2 \in A_2\}) = P(\{\omega \in \Omega : \omega_1 \in A_1 \land \omega_2 \in A_2\})$$
$$= \frac{|A_1| \cdot |A_2|}{|\Omega|} = \frac{|A_1| \cdot |A_2|}{36}$$

and according to Example 9 for i = 1, 2

$$P(\{X_i \in A_i\}) = \frac{|A_i|}{6}.$$

Hence X_1 and X_2 are independent.

(ii) For $\mathfrak{X} = \{1, \dots, 12\}$, $A_1 = \{6\}$ and $B = \{2\}$ we have

$$P(\lbrace X_1 \in A_1 \rbrace \cap \lbrace S \in B \rbrace) = P(\lbrace \omega \in \Omega \colon \omega_1 = 6 \land \omega_1 + \omega_2 = 2 \rbrace)$$
$$= P(\varnothing) = 0$$

as well as $P({X_1 \in A_1}) > 0$ and $P({S \in B}) > 0$. Hence X_1 and S are not independent.

Proposition 15 (Criterion for independence). X_1, \ldots, X_n are independent if and only if for all $x_1, \ldots, x_n \in \mathfrak{X}$ we have

$$P\left(\bigcap_{i=1}^{n} \{X_i = x_i\}\right) = \prod_{i=1}^{n} p_{X_i}(x_i).$$
 (2)

Proof. " \Rightarrow ": Take $A_i = \{x_i\}$.

" \Leftarrow ": Since \mathfrak{X} is countable, every $A_i \subseteq \mathfrak{X}$ can be expressed as a countable union $A_i = \bigcup_{x_i \in A_i} \{x_i\}$ of pairwise disjoint sets. Use the σ-additivity of P and (2). [...]

Remark 16. Consider the special case of n = 2 and $\mathfrak{X} = \{0, \dots, k\}$ for some $k \in \mathbb{N}$. Put

$$p_{i,j} = P(\{X_1 = i\} \cap \{X_2 = j\})$$

and

$$p_{i,\bullet} = P(\{X_1 = i\}\})$$
 and $p_{\bullet,j} = P(\{X_2 = j\}\})$

for $i, j \in \{0, \dots, k\}$. Clearly, we have

$$p_{i,\bullet} = \sum_{j=0}^{k} p_{i,j}$$
 and $p_{\bullet,j} = \sum_{i=0}^{k} p_{i,j}$

for all $i, j \in \{0, ..., k\}$. The corresponding *contingency table* is given by Table II.1. Proposition 15 shows that

$$X_1, X_2$$
 independent $\Leftrightarrow \forall i, j \in \{0, \dots, k\} : p_{i,j} = p_{i,\bullet} \cdot p_{\bullet,j}$

X_2 X_1	0		k	Σ
0	$p_{0,0}$		$p_{0,k}$	$p_{0,ullet}$
:	:	٠.	:	÷
k	$p_{k,0}$		$p_{k,k}$	$p_{k,ullet}$
\sum	$p_{\bullet,0}$		$p_{ullet,k}$	1

Table II.1: Contingency table from Remark 16.

5 Empirical Distribution

In the sequel let $(\Omega, \mathcal{P}(\Omega), P)$ be a discrete probability space and let $X : \Omega \to \mathfrak{X}$ be a random variable with a countable set $\mathfrak{X} \subseteq \mathbb{R}$.

We consider the case where the set \mathfrak{X} of possible realizations is known but the distribution P_X is unknown. Instead, a *sample* (data set)

$$x_1, \dots, x_N \in \mathfrak{X} \tag{3}$$

consisting of realizations of N independent repetitions of the random experiments is available.

Question: Can we approximately determine the probability mass function p_X of X?

Definition 1. Given the sample (3) the relative frequency of $x \in \mathfrak{X}$ is given by

$$\widehat{p}(x) = \frac{|\{\ell \in \{1, \dots, N\} \colon x_{\ell} = x\}|}{N}$$

$$= \frac{\text{number of elements of the sample equal to } x}{N}.$$

Remark 2. For $p = \widehat{p}$ we have (1) in Proposition 2.2(ii). According to Proposition 2.2(iii), see also Proposition 4.5, we obtain a probability distribution \widehat{P} on \mathfrak{X} satisfying

$$\widehat{P}(A) = \sum_{x \in A} \widehat{p}(x) = \frac{|\{\ell \in \{1, \dots, N\} : x_{\ell} \in A\}|}{N}$$

$$= \frac{\text{number of elements of the sample with values in } A}{N}$$

for $A \subseteq \mathfrak{X}$.

Definition 3. \widehat{P} is called *empirical distribution* of the sample (3).

Remark 4. A rod graph can be used to illustrate empirical distributions in terms of relative frequencies. Based on the scale of measure we distinguish the following types:

(i) Nominal scale: Elements of \mathfrak{X} indicate a name (operations $=, \neq$). Example: gender (male (0), female (1)).

X_2 X_1	0		k	Σ
0	$\widehat{p}_{0,0}$		$\widehat{p}_{0,k}$	$\widehat{p}_{0,ullet}$
:	:	٠.	:	:
k	$\widehat{p}_{k,0}$		$\widehat{p}_{k,k}$	$\widehat{p}_{k,ullet}$
\sum	$\widehat{p}_{ullet,0}$		$\widehat{p}_{ullet,k}$	1

Table II.2: Contingency table for empirical distribution from Remark 6.

- (ii) Ordinal scale: Elements of \mathfrak{X} allow for a ranking (operations <,>,=). Example: rank order.
- (iii) Metric (cardinal) scale: Elements of \mathfrak{X} are numeric and allow for arithmetic operations. Examples: time, temperature, sales.

Remark 5. The case of a multivariate random variable (random vector)

$$X = (X_1, \ldots, X_n) \colon \Omega \to \mathfrak{X}$$

with an at most countably infinite set $\mathfrak{X} \subseteq \mathbb{R}^n$ is treated analogously.

Remark 6 (Counterpart of Remark 4.16). Consider the special case of two random variables $(X_1, X_2) : \Omega \to \mathfrak{X}$ and $\mathfrak{X} = \{0, \dots, k\}^2$ with $k \in \mathbb{N}$. Put

$$\widehat{p}_{i,j} = \frac{|\{\ell \in \{1, \dots, N\} : x_{\ell} = (i, j)\}|}{N}$$

and

$$\widehat{p}_{i,\bullet} = \frac{|\{\ell \in \{1,\dots,N\} \colon x_{\ell,1} = i\}|}{N}, \quad \widehat{p}_{\bullet,j} = \frac{|\{\ell \in \{1,\dots,N\} \colon x_{\ell,2} = j\}|}{N}$$

for $i, j \in \{0, ..., k\}$. We clearly have

$$\widehat{p}_{i,\bullet} = \sum_{j=0}^{k} \widehat{p}_{i,j}$$
 and $\widehat{p}_{\bullet,j} = \sum_{i=0}^{k} \widehat{p}_{i,j}$

for all $i, j \in \{0, ..., k\}$. The corresponding contingency table is given by Table II.2. The random variables X_1 and X_2 are assumed to be independent if and only if

$$\widehat{p}_{i,j} \approx \widehat{p}_{i\bullet} \cdot \widehat{p}_{\bullet,j}$$

for all $i, j \in \{0, ..., k\}$.

Example 7. The relative frequencies of tossing two fair coins, see Example 2.5 (one coin tossed twice independently), resulting from a computer simulation with sample size $N = 10^3$ is shown in Figure 5.1. The corresponding contingency table for

$$X_1(\omega) = \omega_1, \quad X_2(\omega) = \omega_2$$

with $\omega = (\omega_1, \omega_2) \in \Omega$ is shown in Table II.3.

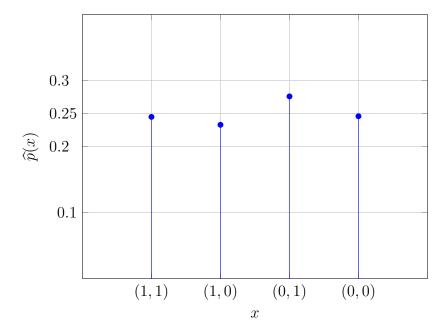

Figure 5.1: Relative frequencies of tossing two fair coins based on 10^3 repetitions.

X_2 X_1	0	1	Σ
0	0.246	0.276	0.522
1	0.233	0.245	0.478
Σ	0.479	0.521	1

Table II.3: Contingency table for empirical distribution in Figure 5.1.

6 Special Discrete Distributions

In this section we discuss several discrete probability distributions that serve as standard models for special random experiments.

Binomial Distribution

Consider a random experiment with the two outcomes 1 (success) and 0 (failure) that is repeated n times independently. This can be modeled by

- (i) parameters $n \in \mathbb{N}$ (number of repetitions) and $p \in [0,1]$ (probability of success),
- (ii) independent and identically distributed (i.i.d.) random variables X_1, \ldots, X_n satisfying

$$p = P({X_i = 1}) = 1 - P({X_i = 0})$$

for all $i = 1, \ldots, n$.

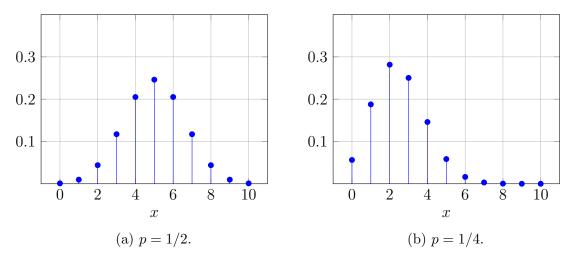

Figure 6.1: Probability mass functions of $X \sim B(10, p)$ with p = 1/2 and p = 1/4.

Put

$$S_n = \sum_{i=1}^n X_i$$

and note that for $\omega \in \Omega$ we have

$$S_n(\omega) = |\{i \in \{1, \dots, n\} : X_i(\omega) = 1\}|,$$

i.e., the number of successes is given by S_n .

Proposition 1. For $k \in \{0, ..., n\}$ we have

$$P(\{S_n = k\}) = \binom{n}{k} \cdot p^k \cdot (1-p)^{n-k}.$$

Definition 2. A random variable X is binomially distributed with parameters $n \in \mathbb{N}$ und $p \in [0, 1]$ if

$$P(\lbrace X = k \rbrace) = \binom{n}{k} \cdot p^k \cdot (1 - p)^{n - k}$$

for all $k \in \{0, ..., n\}$.

Notation: $X \sim B(n, p)$.

Statistical Problem. Given n and k (by a sample), estimate p.

Example 3. The probability mass functions of $X \sim B(n, p)$ for $n \in \{10, 50\}$ and different values of $p \in [0, 1]$ are illustrated in Figure 6.1 and Figure 6.2.

Proposition 4. Let X and Y be independent with $X \sim B(n, p)$ and $Y \sim B(m, p)$ for $m, n \in \mathbb{N}$ and $p \in [0, 1]$. Then we have

$$X + Y \sim B(n + m, p).$$

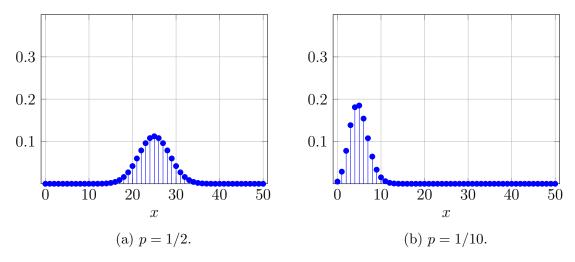

Figure 6.2: Probability mass functions of $X \sim B(50, p)$ with p = 1/2 and p = 1/10.

Multinomial Distribution

Consider a random experiment with outcomes $0, \ldots, m-1$ that is repeated n times independently. This can be modeled by

- (i) parameters $n \in \mathbb{N}$ (number of repetitions), $m \in \mathbb{N} \setminus \{1\}$ (number of outcomes), and $p_0, \dots, p_{m-1} \in [0, 1]$ such that $\sum_{j=0}^{m-1} p_j = 1$ (probabilities of m outcomes),
- (ii) i.i.d. random variables X_1, \ldots, X_n satisfying

$$P(\{X_i = j\}) = p_j$$

for all i = 1, ..., n and j = 0, ..., m - 1.

Put

$$S_j(\omega) = |\{i \in \{1, \dots, n\} \colon X_i(\omega) = j\}|$$

for $\omega \in \Omega$ and $j \in \{0, ..., m-1\}$, i.e., S_j is the number of random experiments with outcome j, and put

$$S = (S_0, \dots, S_{m-1}).$$

Remark 5. (i) For j = 0, ..., m - 1 we have $S_j \sim B(n, p_j)$.

(ii) The random variables S_0, \ldots, S_{m-1} are not independent in general. We have

$$\sum_{j=0}^{m-1} S_j(\omega) = n$$

for all $\omega \in \Omega$.

Proposition 6. For $k = (k_0, \ldots, k_{m-1}) \in \mathbb{N}_0^m$ with $\sum_{j=0}^{m-1} k_j = n$ we have

$$P(\{S=k\}) = \frac{n!}{k_0! \cdots k_{m-1}!} \cdot p_0^{k_0} \cdots p_{m-1}^{k_{m-1}}.$$

Definition 7. A random vector X follows a multinomial distribution with parameters $n \in \mathbb{N}$ and $p_0, \ldots, p_{m-1} \in [0, 1]$ with $\sum_{j=0}^{m-1} p_j = 1$ if

$$P(\{X=k\}) = \frac{n!}{k_0! \cdots k_{m-1}!} \cdot p_0^{k_0} \cdots p_{m-1}^{k_{m-1}}$$

for all $k = (k_0, ..., k_{m-1}) \in \mathbb{N}_0^m$ with $\sum_{j=0}^{m-1} k_j = n$. Notation: $X \sim M(n, p_0, ..., p_{m-1})$.

Hypergeometric Distribution

Consider a sample of size $n \in \mathbb{N}$ drawn without replacement from a set with $N \in \mathbb{N}$ elements consisting of K elements of type "success" and N-K elements of type "failure". This can be modeled by

- (i) parameters $N, K, n \in \mathbb{N}$ with $n \leq N$ and $K \leq N$,
- (ii) the uniform distribution P on

$$\Omega = \{ \omega \subseteq \{1, \dots, N\} \colon |\omega| = n \}.$$

Put

$$X(\omega) = |\omega \cap \{1, \dots, K\}|$$

for $\omega \in \Omega$, i.e., $\omega \subseteq \{1, ..., N\}$ with $|\omega| = n$, to count the number of successes contained in the subset ω .

A typical application is given by quality control.

Remark 8. Proposition ??.?? shows

$$|\Omega| = \binom{N}{n}.$$

Proposition 9. For $k \in \mathbb{N}_0$ with

$$n - (N - K) \le k \le \min(n, K) \tag{4}$$

we have

$$P(\lbrace X=k\rbrace) = \frac{\binom{K}{k} \cdot \binom{N-K}{n-k}}{\binom{N}{n}}.$$
 (5)

Definition 10. A random variable X is hypergeometrically distributed with parameters $N, K, n \in \mathbb{N}$ with $n \leq N$ and $K \leq N$ if (5) holds for all $k \in \mathbb{N}_0$ with (4). Notation: $X \sim H(N, K, n)$.

Statistical Problem. (i) Given N, n, and k (by a sample), estimate K.

(ii) Given K, n, and k (by a sample), estimate N.

Proposition 11. Let $X_N \sim H(N, K_N, n)$ for $N \in \mathbb{N}$ such that

$$\lim_{N\to\infty}\frac{K_N}{N}\in \left]0,1\right[.$$

Put $p = \lim_{N \to \infty} \frac{K_N}{N}$. Then we have

$$\lim_{N \to \infty} P(\{X_N = k\}) = \binom{n}{k} \cdot p^k \cdot (1-p)^{n-k}$$

for all $k \in \{0, ..., n\}$.

Proof. By assumption, we have $\lim_{N\to\infty} K_N = \infty$. Hence $k\in\mathbb{N}_0$ together with condition (4) becomes $k\in\{0,\ldots,n\}$ if $N\in\mathbb{N}$ is large enough. In this case we have

$$P(\{X_{N} = k\}) = \frac{\binom{K_{N}}{k} \cdot \binom{N-K_{N}}{n-k}}{\binom{N}{n}}$$

$$= \frac{K_{N} \cdot (K_{N} - 1) \cdot \dots \cdot (K_{N} - k + 1)}{1 \cdot 2 \cdot \dots \cdot k} \cdot \frac{(N - K_{N}) \cdot (N - K_{N} - 1) \cdot \dots \cdot (N - K_{N} - (n - k) + 1)}{1 \cdot 2 \cdot \dots \cdot (n - k)} \cdot \frac{1 \cdot 2 \cdot \dots \cdot (n - k)}{N \cdot (N - 1) \cdot \dots \cdot (N - k + 1) \cdot (N - k) \cdot \dots \cdot (N - n + 1)}$$

$$= \binom{n}{k} \cdot \frac{K_{N} \cdot (K_{N} - 1) \cdot \dots \cdot (K_{N} - k + 1)}{N \cdot (N - 1) \cdot \dots \cdot (N - k + 1)} \cdot \frac{(N - K_{N}) \cdot (N - K_{N} - 1) \cdot \dots \cdot (N - K_{N} - (n - k) + 1)}{(N - k) \cdot \dots \cdot (N - n + 1)}$$

for $k \in \{0, ..., n\}$. Moreover, the orange and the green factor tend to p^k and $(1-p)^{n-k}$, respectively, as $N \to \infty$.

Example 12. The probability mass functions of $X \sim H(100, 20, 10)$ and $Y \sim B(10, 1/5)$ are illustrated in Figure 6.3. As indicated by Proposition 11, the distance

$$\max_{k \in \{0,...,n\}} |p_X(k) - p_Y(k)|$$

with n = 10 is rather small.

Poisson Distribution

Proposition 13 (Poisson limit theorem). Let $X_n \sim B(n, p_n)$ for $n \in \mathbb{N}$ such that

$$\lim_{n\to\infty} n \cdot p_n \in \left]0,\infty\right[.$$

Put $\lambda = \lim_{n \to \infty} n \cdot p_n$. Then we have

$$\lim_{n \to \infty} P(\{X_n = k\}) = \exp(-\lambda) \cdot \frac{\lambda^k}{k!}$$

for all $k \in \mathbb{N}_0$.

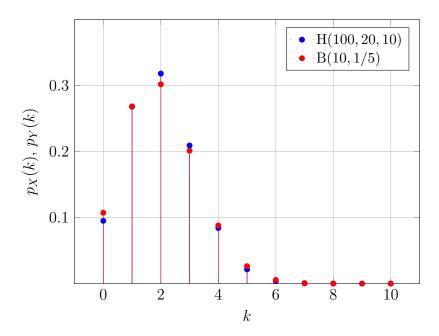

Figure 6.3: Probability mass functions of $X \sim H(100, 20, 10)$ and $Y \sim B(10, 1/5)$.

Proof. For $k \in \mathbb{N}_0$ and $n \in \mathbb{N}$ with $n \geq k$ we have

$$P(\lbrace X_n = k \rbrace) = \binom{n}{k} \cdot p_n^k \cdot (1 - p_n)^{n-k}$$

$$= \underbrace{\frac{n \cdot (n-1) \cdot \dots \cdot (n-k+1)}{n^k}}_{\rightarrow 1} \cdot \underbrace{\frac{(n \cdot p_n)^k}{k!}}_{\rightarrow \lambda^k/k!} \cdot \left(1 - \frac{n \cdot p_n}{n}\right)^n \cdot (1 - p_n)^{-k}.$$

By assumption, we have $\lim_{n\to\infty} p_n = 0$ and thus $\lim_{n\to\infty} (1-p_n)^{-k} = 1$. Moreover, every convergent sequence $(\lambda_n)_{n\in\mathbb{N}}$ with $\lambda = \lim_{n\to\infty} \lambda_n$ satisfies

$$\lim_{n \to \infty} \left(1 + \frac{\lambda_n}{n} \right)^n = \exp(\lambda).$$

Hence we get

$$\lim_{n \to \infty} P(\{X_n = k\}) = \frac{\lambda^k}{k!} \cdot \exp(-\lambda).$$

Remark 14. For all $\lambda \in \mathbb{R}$ we have $\sum_{k=0}^{\infty} \frac{\lambda^k}{k!} = \exp(\lambda)$.

Definition 15. A random variable X follows a Poisson distribution with parameter $\lambda \in]0, \infty[$ if

$$P({X = k}) = \exp(-\lambda) \cdot \frac{\lambda^k}{k!}$$

for all $k \in \mathbb{N}_0$.

Notation: $X \sim \text{Poi}(\lambda)$.

Example 16. The probability mass functions of $X \sim \text{Poi}(\lambda)$ with $\lambda \in \{1/2, 3\}$ are illustrated in Figure 6.4. Moreover, the probability mass functions of $Y \sim B(50, 1/10)$

and $Z \sim \text{Poi}(5)$ are illustrated in Figure 6.5. As indicated by Proposition 13, the distance

$$\max_{k \in \{0, ..., n\}} |p_Y(k) - p_Z(k)|$$

with n = 50 is rather small.

Typical examples where a Poisson distribution serves as the stochastic model include

- (i) number of decay events from a radioactive source within a certain time interval,
- (ii) incoming calls in a call center per hour.

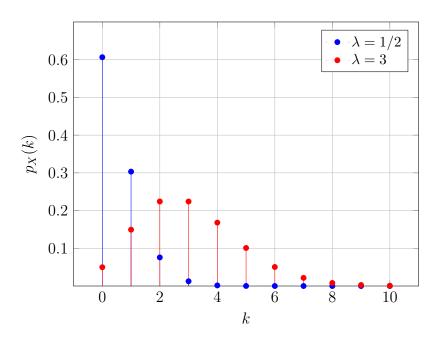

Figure 6.4: Probability mass functions of $X \sim \text{Poi}(\lambda)$ with $\lambda = 1/2$ and $\lambda = 3$.

Geometric Distribution

Consider a random experiment with the two outcomes 1 (success) and 0 (failure) that is repeated n times independently. This can be modeled by

- (i) parameters $n \in \mathbb{N}$ (number of repetitions) and $p \in [0, 1]$ (probability of success),
- (ii) i.i.d. random variables X_1, \ldots, X_n satisfying

$$p = P(\{X_i = 1\}) = 1 - P(\{X_i = 0\})$$

for all $i = 1, \ldots, n$.

For $\omega \in \Omega$ we put

$$T_n(\omega) = 0$$

if

$$X_1(\omega) = \ldots = X_n(\omega) = 0,$$

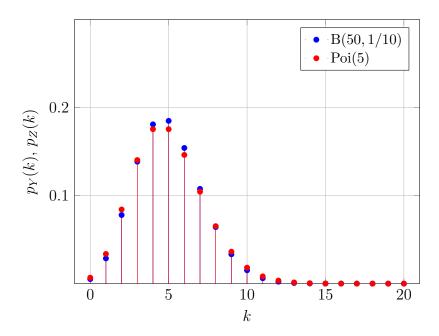

Figure 6.5: Probability mass functions of $Y \sim B(50, 1/10)$ and $Z \sim Poi(5)$.

and we put

$$T_n(\omega) = \min\{k \in \{1, \dots, n\} \colon X_k(\omega) = 1\}$$

otherwise, i.e., if $\{k \in \{1,\ldots,n\}: X_k(\omega) = 1\} \neq \emptyset$. Note that T_n describes the (discrete) waiting time until the first success occurs within n trials.

Remark 17. (i) For $n \in \mathbb{N}$ and $k \in \{0, ..., n\}$ we have

$$P(\lbrace T_n = k \rbrace) = \begin{cases} (1-p)^{k-1} \cdot p, & \text{if } k \in \lbrace 1, \dots, n \rbrace, \\ (1-p)^n, & \text{if } k = 0. \end{cases}$$

In particular, we have $\lim_{n\to\infty} P(\{T_n=0\}) = 0$.

(ii) For all $p \in (0, 1]$ we have $\sum_{k=1}^{\infty} (1 - p)^{k-1} = 1/p$.

Definition 18. A random variable X is geometrically distributed with parameter $p \in [0, 1]$ if

$$P({X = k}) = (1 - p)^{k-1} \cdot p$$

for all $k \in \mathbb{N}$.

Notation: $X \sim \text{Geo}(p)$.

7 Expected Value and Variance

In the sequel let $(\Omega, \mathcal{P}(\Omega), P)$ be a discrete probability space and let $X : \Omega \to \mathfrak{X}$ be a random variable with a countable set $\mathfrak{X} \subseteq \mathbb{R}$.

Expected Value

Definition 1. If $\sum_{\omega \in \Omega} |X(\omega)| \cdot P(\{\omega\}) < \infty$, the expected value (or expectation, mean) of X is defined by

$$E(X) = \sum_{\omega \in \Omega} X(\omega) \cdot P(\{\omega\}).$$

Remark 2. If $|\Omega| < \infty$, the condition $\sum_{\omega \in \Omega} |X(\omega)| \cdot P(\{\omega\}) < \infty$ in Definition 1 is trivially satisfied for every random variable X.

Example 3. Let $|\Omega| < \infty$, and let P be the uniform distribution on Ω . Then we have

$$E(X) = \frac{1}{|\Omega|} \cdot \sum_{\omega \in \Omega} X(\omega).$$

In particular, for $\Omega = \{0, \dots, 36\}$ and

$$X(\omega) = \begin{cases} 1, & \text{if } \omega \text{ is odd,} \\ -1, & \text{if } \omega \text{ is even,} \end{cases}$$

we have (Roulette, outside bet "odd")

$$E(X) = -\frac{1}{37}.$$

Example 4. If X is constant, i.e., $X(\omega) = b \in \mathbb{R}$ for all $\omega \in \Omega$, we have

$$E(X) = b \cdot \sum_{\omega \in \Omega} P(\{\omega\}) = b.$$

In the sequel let X and Y be random variables on $(\Omega, \mathcal{P}(\Omega), P)$. Moreover, we tacitly assume that the involved random variables satisfy the condition on absolute convergence in Definition 1.

Proposition 5.

(i) For all $c \in \mathbb{R}$ we have

$$E(c \cdot X + Y) = c \cdot E(X) + E(Y).$$
 (linearity)

(ii) If $X(\omega) \leq Y(\omega)$ for all $\omega \in \Omega$, we have

$$E(X) \le E(Y)$$
. (monotonicity)

Proof. ad (i): For $c \in \mathbb{R}$ we have

$$\begin{split} \mathbf{E}(c \cdot X + Y) &= \sum_{\omega \in \Omega} (c \cdot X(\omega) + Y(\omega)) \cdot P(\{\omega\}) \\ &= c \cdot \sum_{\omega \in \Omega} X(\omega) \cdot P(\{\omega\}) + \sum_{\omega \in \Omega} Y(\omega) \cdot P(\{\omega\}) = c \cdot \mathbf{E}(X) + \mathbf{E}(Y). \end{split}$$

ad (ii): Since $P(\{\omega\}) \geq 0$ for all $\omega \in \Omega$, we obtain

$$E(X) = \sum_{\omega \in \Omega} X(\omega) \cdot P(\{\omega\}) \le \sum_{\omega \in \Omega} Y(\omega) \cdot P(\{\omega\}) = E(Y).$$

Proposition 6. For every function $g: \mathbb{R} \to \mathbb{R}$ we have

$$E(g(X)) = \sum_{x \in \mathfrak{X}} g(x) \cdot p_X(x).$$

In particular, the expected value of X only depends on the distribution of X.

Proposition 7 (Expected value of special discrete distributions).

(i) For $X \sim B(n, p)$ with $n \in \mathbb{N}$ and $p \in [0, 1]$ we have

$$E(X) = n \cdot p$$
.

(ii) For $X \sim H(N, K, n)$ with $N, K, n \in \mathbb{N}$, $n \leq N$, and $K \leq N$ we have

$$E(X) = \frac{n \cdot K}{N}.$$

(iii) For $X \sim \text{Poi}(\lambda)$ with $\lambda > 0$ we have

$$E(X) = \lambda$$
.

(iv) For $X \sim \text{Geo}(p)$ with $p \in [0, 1]$ we have

$$E(X) = \frac{1}{p}.$$

Proposition 8 (Product of independent random variables). If X and Y are independent, we have

$$E(X \cdot Y) = E(X) \cdot E(Y).$$

Variance

Definition 9. If $\sum_{\omega \in \Omega} |X(\omega)|^2 \cdot P(\{\omega\}) < \infty$, the *variance* of X is defined by

$$\sigma_X^2 = \operatorname{Var}(X) = \operatorname{E}\left(\left(X - \operatorname{E}(X)\right)^2\right).$$

In this case $\sigma_X = \sqrt{\operatorname{Var}(X)}$ is called *standard deviation* of X.

In the sequel we tacitly assume that the involved random variables satisfy the condition on absolute convergence in Definition 9. See also Remark 2.

Remark 10. Proposition 6 with $g(x) = (x - E(X))^2$ shows

$$Var(X) = \sum_{x \in \mathfrak{X}} (x - E(X))^2 \cdot p_X(x).$$

In particular, the variance of X only depends on the distribution of X.

Example 11. For $X \sim B(1, p)$ with $p \in [0, 1]$ we have

$$Var(X) = (0 - p)^{2} \cdot P(\{X = 0\}) + (1 - p)^{2} \cdot P(\{X = 1\})$$
$$= p^{2} \cdot (1 - p) + (1 - p)^{2} \cdot p$$
$$= p \cdot (1 - p).$$

As a function of p, Var(X) attains its maximum at p = 1/2, and Var(X) attains its minimum at p = 0 and p = 1.

Proposition 12.

(i) We have

$$Var(X) = E(X^2) - (E(X))^2.$$

(ii) For all $a, b \in \mathbb{R}$ we have

$$Var(a \cdot X + b) = a^2 \cdot Var(X).$$

Proof. ad (i): Using Proposition 5.(i) and Example 4 we obtain

$$Var(X) = E((X - E(X))^{2})$$

$$= E(X^{2} - 2X \cdot E(X) + (E(X))^{2})$$

$$= E(X^{2}) - 2 \cdot (E(X))^{2} + (E(X))^{2} = E(X^{2}) - (E(X))^{2}.$$

ad (ii): By Proposition 5.(i) we have

$$Var(a \cdot X + b) = E\left(\left(aX + b - E(aX + b)\right)^{2}\right)$$

$$= E\left(\left(aX + b - aE(X) - b\right)^{2}\right)$$

$$= E\left(a^{2} \cdot \left(X - E(X)\right)^{2}\right) = a^{2} \cdot Var(X).$$

Proposition 13 (Bienaymé's identity). If X and Y are independent, we have

$$Var(X + Y) = Var(X) + Var(Y).$$

Proof. Using Proposition 12.(i) and Proposition 5.(i) we obtain

$$Var(X + Y) = E((X + Y)^{2}) - (E(X + Y))^{2}$$

$$= E(X^{2} + Y^{2} + 2XY) - (E(X) + E(Y))^{2}$$

$$= E(X^{2}) + E(Y^{2}) + 2E(XY) - (E(X))^{2} - (E(Y))^{2} - 2E(X)E(Y)$$

$$= Var(X) + Var(Y) + 2 \cdot (E(XY) - E(X)E(Y)).$$

Since X, Y are independent, we may apply Proposition 8.

Proposition 14 (Variance of special discrete distributions).

(i) For $X \sim B(n, p)$ with $n \in \mathbb{N}$ and $p \in [0, 1]$ we have

$$Var(X) = n \cdot p \cdot (1 - p).$$

(ii) For $X \sim H(N, K, n)$ with $N, K, n \in \mathbb{N}, n \leq N, K \leq N$, and $N \geq 2$ we have

$$Var(X) = \frac{n \cdot (N - n) \cdot (N - K) \cdot K}{N^2 \cdot (N - 1)}.$$

(iii) For $X \sim \text{Poi}(\lambda)$ with $\lambda > 0$ we have

$$Var(X) = \lambda$$
.

(iv) For $X \sim \text{Geo}(p)$ with $p \in]0,1]$ we have

$$Var(X) = \frac{1 - p}{p^2}.$$

Proposition 15 (Chebyshev's inequality). For all $\varepsilon > 0$ we have

$$P(\{|X - E(X)| \ge \varepsilon\}) \le \frac{Var(X)}{\varepsilon^2}.$$

Proof. For $\varepsilon > 0$ and $A \in \mathcal{P}(\Omega)$ given by

$$A = \{|X - \mathbf{E}(X)| \ge \varepsilon\} = \{\omega \in \Omega \colon (X(\omega) - \mathbf{E}(X))^2 \ge \varepsilon^2\}$$

we obtain

$$\varepsilon^{2} \cdot P(A) = \sum_{\omega \in A} \varepsilon^{2} \cdot P(\{\omega\}) \leq \sum_{\omega \in A} (X(\omega) - E(X))^{2} \cdot P(\{\omega\})$$
$$\leq \sum_{\omega \in \Omega} (X(\omega) - E(X))^{2} \cdot P(\{\omega\}) = Var(X). \quad \Box$$

Sample Mean and Sample Variance

In the sequel let

$$x_1,\ldots,x_N\in\mathfrak{X}$$

be a sample with relative frequencies $\widehat{p}(x)$ for $x \in \mathfrak{X}$, see Section 5.

Definition 16. The sample mean (or empirical mean) \overline{x}_N is defined by

$$\overline{x}_N = \frac{1}{N} \cdot \sum_{i=1}^N x_i.$$

Remark 17. We have

$$\overline{x}_N = \frac{1}{N} \cdot \sum_{x \in \mathfrak{X}} x \cdot |\{\ell \in \{1, \dots, N\} \colon x_\ell = x\}| = \sum_{x \in \mathfrak{X}} x \cdot \widehat{p}(x).$$

Hence \overline{x}_N is the expected value of the associated empirical distribution.

Definition 18. Let $N \in \mathbb{N}$ with $N \geq 2$. The sample variance s_N^2 is defined by

$$s_N^2 = \frac{1}{N-1} \cdot \sum_{i=1}^N (x_i - \overline{x}_N)^2.$$

Moreover, $s_N = \sqrt{s_N^2}$ is called sample standard deviation.

Remark 19. We have

$$s_N^2 = \frac{1}{N-1} \cdot \left(\sum_{i=1}^N x_i^2 - N \cdot \overline{x}_N^2 \right).$$

Hence $(N-1)/N \cdot s_N^2$ is the variance of the associated empirical distribution.

Chapter III

Probability Theory – General Case

In Chapter II we restricted ourselves to probability spaces $(\Omega, \mathcal{P}(\Omega), P)$ and random variables $X : \Omega \to \mathfrak{X}$ where Ω and $\mathfrak{X} \subseteq \mathbb{R}$ were countable. In this chapter we consider sets Ω and $\mathfrak{X} \subseteq \mathbb{R}$ with possibly uncountably many elements. In this case it is in general not possible anymore

- (i) to assign probabilities to arbitrary subsets $A \in \mathcal{P}(\Omega)$ of Ω ,
- (ii) to assign probabilities $P(X \in A)$ for arbitrary subsets $A \in \mathcal{P}(\mathbb{R})$ of \mathbb{R} ,

see, e.g., [Georgii, pp. 8-9].

In order to overcome this problem, the event spaces $\mathcal{P}(\Omega)$ and $\mathcal{P}(\mathbb{R})$ are replaced by smaller collections of subsets that do not contain the "problematic" subsets. These smaller collections are of the following type.

Definition 1. A collection $\mathcal{A} \subset \mathcal{P}(\Omega)$ of subsets of Ω is a σ -algebra (over Ω) if

- (i) $\Omega \in \mathcal{A}$,
- (ii) $A \in \mathcal{A} \Rightarrow A^{\mathsf{c}} \in \mathcal{A}$,
- (iii) $A_1, A_2, \ldots \in \mathcal{A} \implies \bigcup_{i=1}^{\infty} A_i \in \mathcal{A}$.

A probability space is then a triple (Ω, \mathcal{A}, P) , where $\mathcal{P}(\Omega)$ is consistently replaced by a σ -algebra \mathcal{A} in Definition II.1.9. In particular, we have $P \colon \mathcal{A} \to \mathbb{R}$.

For the real numbers we consider the so-called *Borel-\sigma-algebra* $\mathfrak{B}(\mathbb{R})$, which contains all open subsets of \mathbb{R} and which is generated by sets of the form

$$]-\infty, b], \quad b \in \mathbb{R}.$$

We stress that every interval is contained in $\mathfrak{B}(\mathbb{R})$. In particular, we have

$$]-\infty,b],[a,b],\{a\}\in\mathfrak{B}(\mathbb{R})$$

for all $a, b \in \mathbb{R}$. Moreover, Definition 1 ensures that unions of intervals and complements thereof are also contained in $\mathfrak{B}(\mathbb{R})$.

A random variable $X: \Omega \to \mathbb{R}$ is a so-called *measurable* function, i.e., we require

$$\forall b \in \mathbb{R} : X^{-1}(]-\infty, b]) \in \mathcal{A}.$$

This property ensures

$${X \in A} = {\omega \in \Omega \colon X(\omega) \in A} \in \mathcal{A}$$

for all $A \in \mathfrak{B}(\mathbb{R})$. Hence we can assign probabilities $P(\{X \in A\})$. In the sequel we disregard measurability issues.

1 Absolutely Continuous Distributions

Aim: Model for continuous quantities as, e.g., waiting time, lifetime, or deviations in a production process.

Basic idea: Replace sums by integrals.

Definition 1. A function $f: \mathbb{R} \to \mathbb{R}$ is a *(probability) density (PDF)* if

$$(\forall x \in \mathbb{R} : f(x) \ge 0) \quad \land \quad \int_{-\infty}^{\infty} f(x) \, \mathrm{d}x = 1.$$

Example 2. The following functions $f_1, f_2, f_3 \colon \mathbb{R} \to \mathbb{R}$ are probability densities:

(i) For $a, b \in \mathbb{R}$ with a < b define

$$f_1(x) = \begin{cases} \frac{1}{b-a}, & \text{if } x \in [a, b], \\ 0, & \text{else.} \end{cases}$$

(ii) For $\lambda > 0$ define

$$f_2(x) = \begin{cases} \lambda \cdot \exp(-\lambda \cdot x), & \text{if } x \ge 0, \\ 0, & \text{else.} \end{cases}$$

(iii) For $\mu \in \mathbb{R}$ and $\sigma > 0$ define

$$f_3(x) = \frac{1}{\sqrt{2\pi\sigma^2}} \cdot \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right), \quad x \in \mathbb{R}.$$

The functions f_2 and f_3 are illustrated in Figure 1.1 and Figure 1.2, respectively.

In the sequel let (Ω, \mathcal{A}, P) be a probability space and let $X : \Omega \to \mathbb{R}$ be a random variable.

Definition 3 (cf. Prop. II.4.5). A random variable X is absolutely continuous if there exists a probability density f_X such that

$$P(\{X \in A\}) = \int_A f_X(x) \, \mathrm{d}x$$

for all $A \in \mathfrak{B}(\mathbb{R})$. In this case f_X is called *(probability) density* of X.

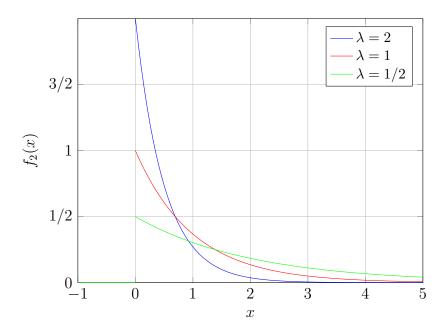

Figure 1.1: Probability density f_2 from Example 2.(ii) with $\lambda \in \{1/2, 1, 2\}$.

Remark 4. Let X be absolutely continuous with density f_X . Then we have

$$\forall x \in \mathbb{R} \colon P(\{X = x\}) = 0.$$

Definition 5. Let X be a random variable with density f_X .

- (i) X is uniformly distributed on [a, b] if $f_X = f_1$ according to Example 2.(i). Notation: $X \sim U(a, b)$.
- (ii) X is exponentially distributed with parameter $\lambda \in]0, \infty[$ if $f_X = f_2$ according to Example 2.(ii). Notation: $X \sim \text{Exp}(\lambda)$.
- (iii) X is normally distributed with parameters $\mu \in \mathbb{R}$ and $\sigma^2 > 0$ if $f_X = f_3$ according to Example 2.(iii). X is standard normally distributed if $\mu = 0$ and $\sigma = 1$. Notation: $X \sim N(\mu, \sigma^2)$.

Remark 6. Let $X \sim \text{Exp}(\lambda)$ with $\lambda > 0$, and let $s, t \geq 0$. Then we have

$$P(\{X \ge t\}) = \int_t^\infty \lambda \cdot \exp(-\lambda x) \, \mathrm{d}x = -\exp(-\lambda \cdot x)|_{x=t}^{x=\infty} = \exp(-\lambda \cdot t).$$

Hence the exponential distribution is memoryless, i.e.,

$$P(\{X \ge s+t\} \,|\, \{X \ge t\}) = \frac{P(\{X \ge s+t\})}{P(\{X \ge t\}} = P(\{X \ge s\}).$$

Application: Modelling of waiting times or durability.

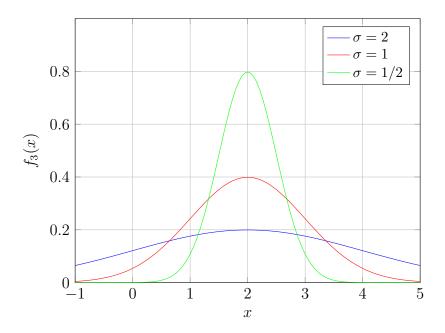

Figure 1.2: Probability density f_3 from Example 2.(iii) with $\mu = 2$ and $\sigma \in \{1/2, 1, 2\}$.

Remark 7 (Continuation of Example 2 and Definition 5).

(i) Let $X \sim \mathrm{U}(0,1)$ and

$$Y = (b - a) \cdot X + a$$

for $a, b \in \mathbb{R}$ with a < b. Then we have $Y \sim \mathrm{U}(a, b)$.

(ii) Let $X \sim \text{Exp}(1)$ and

$$Y = \frac{1}{\lambda} \cdot X$$

for $\lambda > 0$. The change of variables formula shows

$$P(\{Y \in A\}) = P(\{X \in \lambda \cdot A\}) = \int_{\lambda \cdot A} \exp(-x) \, \mathrm{d}x = \int_A \lambda \cdot \exp(-\lambda \cdot x) \, \mathrm{d}x$$

for $A \in \mathfrak{B}([0,\infty[), \text{ and hence } Y \sim \operatorname{Exp}(\lambda).$

(iii) Let $X \sim N(0, 1)$ and

$$Z = \sigma \cdot X + \mu$$

with $\mu \in \mathbb{R}$ and $\sigma > 0$. The change of variables formula shows

$$P(\lbrace Z \in A \rbrace) = \frac{1}{\sqrt{2\pi\sigma^2}} \cdot \int_A \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right) dx$$

for $A \in \mathfrak{B}(\mathbb{R})$, and hence $Z \sim \mathcal{N}(\mu, \sigma^2)$.

In the sequel let X be absolutely continuous with density f_X .

Definition 8 (cf. Prop. II.7.6, and Rem. II.7.10). If $\int_{-\infty}^{\infty} |x| \cdot f_X(x) dx < \infty$, the expected value (or expectation, mean) of X is defined by

$$E(X) = \int_{-\infty}^{\infty} x \cdot f_X(x) \, \mathrm{d}x.$$

If $\int_{-\infty}^{\infty} x^2 \cdot f_X(x) dx < \infty$, the variance of X is defined by

$$\sigma_X^2 = \operatorname{Var}(X) = \int_{-\infty}^{\infty} (x - \operatorname{E}(X))^2 \cdot f_X(x) \, \mathrm{d}x.$$

In this case $\sigma_X = \sqrt{\operatorname{Var}(X)}$ is called *standard deviation* of X.

In the sequel we tacitly assume that the involved random variables satisfy the required integrability conditions for the expected value and the variance.

Proposition 9 (Expected value and variance of special distributions).

(i) For $X \sim U(a, b)$ with a < b we have

$$E(X) = \frac{a+b}{2}, \quad Var(X) = \frac{(b-a)^2}{12}.$$

(ii) For $X \sim \text{Exp}(\lambda)$ with $\lambda > 0$ we have

$$E(X) = \frac{1}{\lambda}, \quad Var(X) = \frac{1}{\lambda^2}.$$

(iii) For $X \sim N(\mu, \sigma^2)$ with $\mu \in \mathbb{R}$ and $\sigma > 0$ we have

$$E(X) = \mu, \quad Var(X) = \sigma^2.$$

Remark 10. Proposition II.7.5 (linearity and monotonicity) and Proposition II.7.8 (product of independent random variables) regarding the expected value as well as Proposition II.7.12 (affine linear transformation), Proposition II.7.13 (Bienaymé's identity), and Proposition II.7.15 (Chebyshev's inequality) regarding the variance are also valid for absolutely continuous random variables.

2 Basic Concepts

In the sequel let (Ω, \mathcal{A}, P) a probability space and let $X : \Omega \to \mathbb{R}$ be a random variable. Recall that $P_X : \mathfrak{B}(\mathbb{R}) \to \mathbb{R}$ is given by

$$P_X(A) = P(\{X \in A\}) = P(\{\omega \in \Omega : X(\omega) \in A\})$$

for $A \in \mathfrak{B}(\mathbb{R})$.

Proposition 1 (cf. Prop. II.4.5). The function P_X is a probability measurable (on \mathbb{R}).

Definition 2 (cf. Def. II.4.6). The function P_X is called *distribution* of X.

Definition 3. X is discrete if there exists a countable set $\mathfrak{X} \subseteq \mathbb{R}$ such that

$$P_X(\mathfrak{X}) = 1.$$

Definition 4 (cf. Def. II.4.8). Two random variables $X_1, X_2 \colon \Omega \to \mathbb{R}$ are identically distributed if

$$P_{X_1}(A) = P_{X_2}(A)$$

for all $A \in \mathfrak{B}(\mathbb{R})$.

Remark 5. Proposition II.4.10 is not correct in general. In particular, for absolutely continuous random variables $X_1, X_2 \colon \Omega \to \mathbb{R}$ we always have

$$P({X_1 = x}) = 0 = P({X_2 = x})$$

for all $x \in \mathbb{R}$.

Definition 6 (cf. Def. II.4.13). Random variables $X_1, \ldots, X_n : \Omega \to \mathbb{R}$ are independent if for all $A_1, \ldots, A_n \in \mathfrak{B}(\mathbb{R})$ we have

$$P\left(\bigcap_{i=1}^{n} \{X_i \in A_i\}\right) = \prod_{i=1}^{n} P(\{X_i \in A_i\}).$$

Remark 7. Proposition II.4.15 is not correct in general.

3 Cumulative Distribution Function and Quantiles

In the sequel let (Ω, \mathcal{A}, P) be a probability space and let $X, Y : \Omega \to \mathbb{R}$ be random variables.

Definition 1. The function $F_X : \mathbb{R} \to [0,1]$ defined by

$$F_X(x) = P(\{X \le x\})$$

is called $cumulative\ distribution\ function\ (CDF)$ of X.

Remark 2. For $x \in \mathbb{R}$ we have

$$P({X > x}) = 1 - P({X \le x}) = 1 - F_X(x).$$

For $u, v \in \mathbb{R}$ with u < v we have

$$P(\{X \in [u, v]\}) = P(\{X \le v\} \setminus \{X \le u\}) = F_X(v) - F_X(u).$$

Proposition 3 (Uniqueness). A cumulative distribution function uniquely determines the distribution, i.e., we have

$$F_X = F_Y \Leftrightarrow P_X = P_Y.$$

Remark 4. Let $Z = c \cdot X + d$ with c > 0 and $d \in \mathbb{R}$. Then we have

$$F_Z(x) = P(\{c \cdot X + d \le x\}) = P(\{X \le (x - d)/c\}) = F_X((x - d)/c))$$

for all $x \in \mathbb{R}$.

At first, we consider absolutely continuous random variables.

Proposition 5 (CDF, absolutely continuous random variables). Let X be absolutely continuous with density f_X . Then we have

$$F_X(x) = \int_{-\infty}^x f_X(y) \, \mathrm{d}y$$

for all $x \in \mathbb{R}$ and F_X is continuous. Moreover, if f_X is continuous at x, then F_X is differentiable at x with $F_X'(x) = f_X(x)$.

Proof. Fundamental theorem of calculus.

Example 6 (CDF, continuation of Example 1.2).

(i) For $Y \sim U(a, b)$ with $a, b \in \mathbb{R}$ and a < b we have

$$F_Y(x) = \begin{cases} 0, & \text{if } x < a, \\ \frac{x - a}{b - a}, & \text{if } x \in [a, b], \\ 1, & \text{if } x > b. \end{cases}$$

Note that $X \sim \mathrm{U}(0,1)$ and $Z = (b-a) \cdot X + a$ implies $Z \sim \mathrm{U}(a,b)$ according to Proposition 3 and Remark 4, see also Remark 1.7.(i).

(ii) For $Y \sim \text{Exp}(\lambda)$ with $\lambda > 0$ we have

$$F_Y(x) = \begin{cases} 0, & \text{if } x < 0, \\ 1 - \exp(-\lambda \cdot x), & \text{if } x \ge 0. \end{cases}$$

Note that $X \sim \text{Exp}(1)$ and $Z = 1/\lambda \cdot X$ implies $Z \sim \text{Exp}(\lambda)$ according to Proposition 3 and Remark 4, see also Remark 1.7.(ii). FIGURE: PDF + CDF

(iii) The CDF of a standard normal distribution is denoted by Φ , i.e., for $x \in \mathbb{R}$ we have

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \cdot \int_{-\infty}^{x} \exp(-y^2/2) \,\mathrm{d}y.$$

Since the corresponding PDF is an even function, we have

$$\Phi(-x) = 1 - \Phi(x)$$

for all $x \in \mathbb{R}$. There is no explicit form of Φ . Function values $\Phi(x)$ can be computed numerically and are listed in Appendix $\boxed{\text{TO DO}}$ for $x \geq 0$.

Note that $X \sim N(0,1)$ and $Z = \sigma \cdot X + \mu$ implies $Z \sim N(\mu, \sigma^2)$ according to Remark 1.7.(iii). Hence, by Remark 4, the CDF of a normal distribution with arbitrary parameters can be reduced to the standard normal case, i.e.,

$$F_Z(x) = F_X((x-\mu)/\sigma) = \Phi\left(\frac{x-\mu}{\sigma}\right)$$

for all $x \in \mathbb{R}$. FIGURE: PDF + CDF

Proposition 7 (CDF, discrete random variables). Let X be a discrete random variable with $P_X(\mathbb{N}_0) = 1$. Then we have

$$F_X(x) = \sum_{i=0}^k p_X(i)$$

for all $k \in \mathbb{N}_0$ and $x \in [k, k+1[$.

Example 8. $X \sim B(6, 1/2)$ FIGURE: PDF + CDF

 $X \sim \text{Poi}(3)$ FIGURE: PDF + CDF

Proposition 9 (Properties of CDFs, general case). Every cumulative distribution function $F_X \colon \mathbb{R} \to [0, 1]$ satisfies

- (i) F_X is non-decreasing,
- (ii) F_X is right-continuous, i.e., $\lim_{y\downarrow x} F_X(y) = F_X(x)$ for all $x\in\mathbb{R}$,
- (iii) $\lim_{x\to\infty} F_X(x) = 1$ and $\lim_{x\to-\infty} F_X(x) = 0$.

Moreover, we have

$$P(\lbrace X = x \rbrace) = F_X(x) - \lim_{y \uparrow x} F_X(y)$$

for all $x \in \mathbb{R}$. In particular, $P(\{X = x\}) = 0$ iff F_X is continuous at x.

Quantiles

Given: Cumulative distribution function F_X and $p \in]0,1[$.

Aim: Find $q \in \mathbb{R}$ with

$$F_X(q) = p. (1)$$

Example 10. Let $X \sim \text{Exp}(\lambda)$ with $\lambda > 0$. For every $p \in]0,1[$ there exists a unique $q \in \mathbb{R}$ satisfying (1), namely

$$q = -\frac{1}{\lambda} \cdot \ln(1 - p).$$

E.g., for $\lambda = 1$ and p = 3/4 we have $q = \ln(4) \approx 1.3863$, see Figure TO DO

Example 11. Let $X \sim B(2, 1/2)$. For $p \in \{1/4, 3/4\}$ there exist infinitely many $q \in \mathbb{R}$ satisfying (1). For $p \in]0, 1[\setminus \{1/4, 3/4\}$ there is no $q \in \mathbb{R}$ satisfying (1).

Definition 12. The *p*-quantile q of F_X (of P_X , of X) is defined by

$$q = \min\{x \in \mathbb{R} \colon F_X(x) \ge p\}.$$

The p-quantile for p = 1/2 is called median of F_X (of P_X , of X). Notation: median m(X).

Example 13 (Continuation of Example 10). Let $X \sim \text{Exp}(\lambda)$ with $\lambda > 0$. The p-quantile of F_X is given by

 $q = -\frac{1}{\lambda} \cdot \ln(1 - p).$

Example 14 (Continuation of Example 11). Let $X \sim B(2, 1/2)$. The *p*-quantile of F_X is given by

$$q = \begin{cases} 0, & \text{if } 0$$

Proposition 15. The p-quantile q of X satisfies

$$P(\{X \leq q\}) \geq p \quad \wedge \quad P(\{X \geq q\}) \geq 1 - p.$$

Moreover, we have

$$|\operatorname{E}(X) - \operatorname{m}(X)| \le \sigma_X.$$

Empirical Distribution Function

As in Section II.5 we consider a sample

$$x_1,\ldots,x_N\in\mathbb{R}$$
.

Definition 16. The *empirical distribution function* $\widehat{F} \colon \mathbb{R} \to [0,1]$ is defined by

$$\widehat{F}(x) = \frac{|\{\ell \in \{1, \dots, N\} : x_{\ell} \le x\}|}{N}.$$

Remark 17. The empirical distribution function is the CDF of the empirical distribution \widehat{P} of the sample. The corresponding order statistics

$$x_{(1)} \le \dots \le x_{(N)}$$

of the sample allows for a straightforward computation of $\widehat{p}(x)$, $\widehat{F}(x)$, and quantiles.

Remark 18. Consider the sample mean \overline{x}_N and the sample median \tilde{x}_N given by

$$\tilde{x}_N = \begin{cases} x_{((N+1)/2)}, & \text{if } N \text{ is odd,} \\ x_{(N/2)}, & \text{if } N \text{ is even.} \end{cases}$$

Question: How many values x_{ℓ} of the sample must be modified in order that \overline{x}_N or \tilde{x}_N attain an arbitrary value?

Answer:

- (i) For \overline{x}_N a single value x_ℓ suffices.
- (ii) Note that

$$\frac{|\{\ell \in \{1, \dots, N\} \colon a \le x_{\ell} \le b\}|}{N} > 1/2$$

implies $\tilde{x}_N \in [a, b]$, see Proposition 15. For \tilde{x}_N we need to modify at least N/2 values.

In this sense the sample median \tilde{x}_N is more robust than the sample mean \bar{x}_N .

Remark 19 (Histogram). TO DO
